Figure 2(b): Fact file on the California condor

- The California condor is the largest North American land bird.
- Condor numbers dramatically declined in the 20th century due to poaching, lead poisoning, and habitat destruction.
- The California condor became extinct in the wild in 1987 when all 22 remaining wild individuals were captured.
- These surviving birds were bred in zoos through captive breeding programs.
- In 1991, condors were reintroduced into the wild.
- The California condor is one of the world’s rarest bird species: population counts in 2012 estimated a total population of 405, including 226 living in the wild and 179 in captivity.
- It is now listed as critically endangered by the IUCN.
- The condor is a scavenger and eats large amounts of carrion.
- It is one of the world’s longest-living birds, with a lifespan of up to 60 years.
- Individual birds have a huge range and have been known to travel up to 250 km in search of carrion.
- The condor is a significant bird to many Californian Native American groups and plays an important role in several of their traditional myths.
- California condors mature and reproduce slowly. They do not breed until they are between six and eight years old, and the female lays only one egg every two years.

Figure 4(a): Threats to the California condor

- Poaching for museum specimens
- Lead poisoning (from eating animal carcasses containing lead shot)
- DDT poisoning
- Birds flying into electric power lines and wind turbines
- Egg collecting
- Habitat destruction
- Hunting by farmers who mistakenly believed the birds had killed farm animals.

Figure 5(a): The captive breeding programme for California condors

- If the egg is removed from a condor nest the mother will lay another. Scientists removed eggs so that mothers would lay more. They did this to increase the overall number of eggs. This meant, however, that they needed to hand rear some chicks.
- Chicks are fed with glove puppets which resemble adult condors to prevent chicks from becoming attached to humans.
- Captive-bred California condors have been trained to avoid power lines and people. Now the number of condor deaths due to power lines has greatly decreased.
- The cost of the captive breeding programme is US\$5 million per year, or roughly US\$13,000 per bird.
- The aim is to have three distinct populations — one wild in California, another wild in Arizona, with a third raised in captivity. Each would have 150 birds and at least 15 breeding pairs.

Figure 7(b): Chumash culture and the condor

The Chumash people historically inhabited the central and southern coastal regions of California. Their descendants still live there now. Old cave paintings show human figures wearing condor feathers for ceremonies and dances. Condors were once sacrificed during rituals. There is a legend that if the condor becomes extinct, so too will the Chumash.

Figure 9(a): Ridley-Tree Condor Preservation Act

- In 2008 it became illegal to use bullets containing lead for hunting game such as deer, bear and elk, in areas designated as California condor range.
- This act only applies in California. In neighbouring states it is not illegal to use lead bullets for game hunting.
- Organisations such as the National Rifle Association oppose the ban on lead bullets.

Figure 10: Compromising to protect condor habitat

Tejon Ranch, located on the map **Figure 5(c)**, is a very large (1000 km²) expanse of hills, valleys and canyons that is a home for the California condor and an important biodiversity hotspot. It is owned by the Tejon Ranch Company.

After months of debate and negotiations, in 2008 an historic agreement was reached between the company and a group of environmental NGOs. The company agreed to preserve 90 % of the property, including feeding grounds for condors. In return the environmental groups agreed not to oppose the building of up to 26 000 homes on the remaining 10 % of the company's land.
